### Unintended Risks of Bank Capital Regulations

**Abstract.** I show that tighter capital regulation can increase aggregate credit risk through heterogeneous lending behavior between banks and nonbank financial intermediaries (NBFIs). Using loan-level mortgage data, I document that NBFIs approve observably similar applicants at higher rates than banks and that NBFI loans have higher default rates. I show that tighter regulation contributed to a shift in credit toward riskier borrowers with higher default rates. I develop a general equilibrium model in which banks and NBFIs choose loan rates and underwriting standards. Tighter regulation raises bank loan rates and tightens underwriting standards, shifting applicants toward NBFIs. NBFIs' looser underwriting standards extend credit to applicants who would otherwise remain unfunded, increasing the aggregate credit risk. The model further shows that tighter regulation can amplify adverse financial shocks.

### Why Is Monetary Policy Less Effective at Low Interest Rates: The Role of Banking Sector

**Abstract.** This paper investigates the effectiveness of monetary policy in a low-interest-rate environment, focusing on how loan and deposit rates respond to changes in nominal interest rates. Using U.S. bank data, I show that deposit rates reach zero when the policy rate falls to about 2 percent, with both deposit and loan rates becoming unresponsive to further cuts below the threshold. Net interest margins do not shrink, preserving banks' equity and lending capacity to additional policy rate cut. Monetary transmission thus weakens well above the zero lower bound, muting the stimulus to loan demand rather than eroding banks' lending capacity. Stabilizing demand-driven recessions near this threshold requires earlier fiscal coordination.

### Equipment, Structures, and the Limits of Investment-Specific Technological Change (with Munseob Lee)

**Abstract.** The falling relative price of equipment, long viewed as the signature of investment-specific technological change (ISTC), has a countervailing force: rising structures prices. We establish four facts: high-income countries' structures prices rise as equipment prices fall; each investment rate falls with its own price; equipment prices predict income growth more strongly than structures prices; and U.S. structures price rises are broad-based. KLEMS data attribute roughly half the post-1996 rise in construction prices, in the U.S. and abroad, to declining construction TFP. We build a two-capital endogenous growth model with structures in production and R&D. Calibrated to the U.S., structures impose a structural drag of 0.52 percentage points per year, partially offsetting a 1.41 percentage point equipment boost. A nested CES extension finds structures-unskilled substitutability alongside equipment-skilled complementarity. These margins shrink the drag by 20-30% and reveal a novel channel whose omission overstates the 1963-2019 U.S. skill premium rise by 30%.
